

Latitudinal diversity and the structure of compositional turnover in Baja California arachnids

Panel A reports coverage-standardized effective genus diversity at common coverage $C = 0.7279$. $q=0$ is genus richness; $q=1$ increasingly weights common genera; $q=2$ places the greatest weight on dominant or frequently detected genera. Values are ballooning-capable / non-ballooning. Panel B is not q -specific: it reports ballooning-minus-non-ballooning contrasts in the additive Baselga replacement and nestedness-resultant components of Jaccard dissimilarity. Points are medians and bars are 2.5th-97.5th percentile intervals from 5,000 paired equal-cell iterations; * marks intervals excluding zero.
